

Comparing our group's consolidated requirements with the AI-generated requirements, we found the AI missed the deposit conflict between store employees and clerks as well as several key rental clerk requirements, invented one requirement that wasn't grounded in any stakeholder need, agreed with our requirements list on fundamental store owner/clerk requirements, and identified several database requirements that we missed.

First, we found the AI missed the conflict in deposit requirements between the store and the customers, silently dropping the store clerk's requirements for deposits and credibility on higher-value gear. The AI also missed store clerk requirements like robust cybersecurity, producing reports and analysis on what gear is being rented most often, and keeping monthly costs of the system at \$10/month or less. From this, it seems highly likely the AI carried hidden biases about the situation that influenced its requirements list.

Second, we also found the AI invented a need that no stakeholder needed: allowing customers to use the website from places with weak internet, such as trailheads. In our stakeholder interviews, we found both the store and the customers only needed website access in store or at home, as customers wanted to focus on their gear and store employees would only use the website from inside the store. Thus, using the website from places with weak internet, like trailheads, is an invented requirement not grounded in any stakeholder needs.

In addition, we found our requirements lists and the AI requirements list agreed over generic rental store requirements, such as having records of each piece of gear, recording when each piece of gear is due, and making the system easy for store employees to pick up with minimal training.

Finally, the AI produced several useful requirements we had not initially considered. These included: supporting about 150 items and about 50 rentals per weekend day without slowing down, each item having its own UUID, allowing customers to rent out multiple pieces of gear at once and return them in any order, backing up the system's data, ensuring only employees can view system data, and record gear condition when it is checked out and when it is returned.
